

Status of the Plug Simulation Tuning

Pedro A. Movilla Fernández (LBNL)

Jet Energy and Resolution Group Meeting

Aug. 23rd, 2006

Overview

- In the Central, the hadronic lateral profile and absolute response are consistently tuned to single isolated track data up to 40 GeV/c
Level of agreement E/p (MC-Data): 1-2% (status CALOR06)
- In the Plug we are currently using a hybrid tuning:
Gen-6 Central lateral profile plus Gen-5 absolute response tuning
 - doesn't fit the E/p data well (see SGM talk of 04/06/06)
 - want to improve picture by a new eta-dependent tuning

This talk:

- 1) Lateral profile tuning update in Plug (almost final).
- 2) How to use the data for the absolute E/p tuning.
- 3) Interdependence between lateral and absolute response.

Track Quality Requirements

- Tracks are extrapolated to PES.
- 7x7 block isolation around target tower.

	COT		Silicon		
	axial	stereo	axial	stereo	z
Crack:	≥ 20	≥ 20	≥ 4	-	-
Plug:	≥ 7	≥ 7	≥ 4	≥ 2	≥ 2

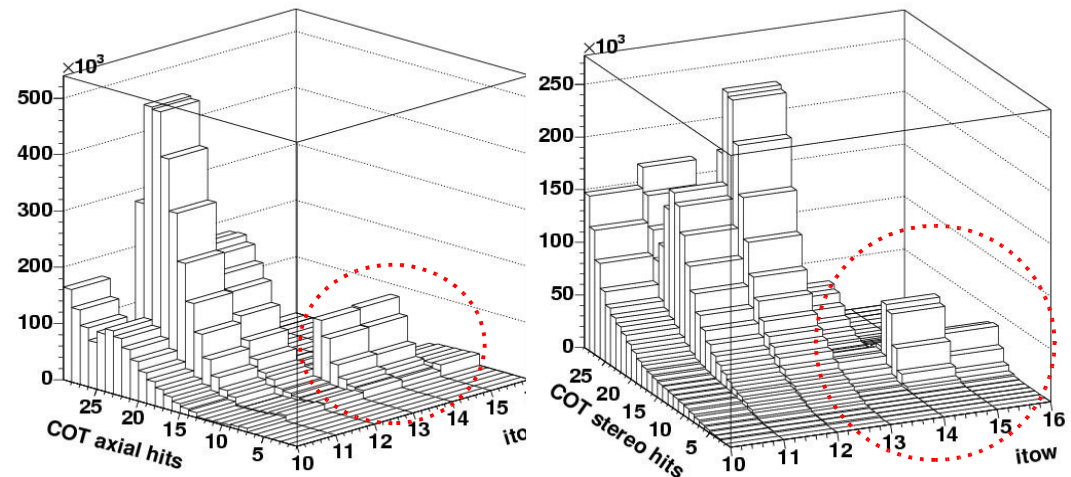

- cut reduces isolated track statistics considerably but is crucial to ensure reasonable E/p measurement.
- target towers >15 not usable

minbias data (gmbs0d)

"Crack" = target towers 10+11

"Plug" = target towers 13-15

Data Samples

- Minimum bias sample (gmbs0d, ~21M events)
- Single Track Trigger data:

- 3, 4, 7 GeV/c thresholds:	gjtc0d	~16M events
- 10 GeV/c threshold:	gjtc0h_stt10	~4M events
- 15 GeV/c threshold:	gjtc0h_stt15	~6M events

...contain single isolated tracks in Plug/Crack as byproduct

Signal Definition

- **E/p profile:**

sig: $\langle E/p \rangle$ in 5 tower strips (3x1) adjacent in η

bck: 1.5 x both side towers

cut: $|\eta^{\text{rel}}| < 0.6$, $|\phi^{\text{rel}}| < 0.6$

relative η coordinates are normalized to tower boundaries

- **Absolute E/p response:**

Crack: sig: EM=3x1 strip, HAD=3x1 strip

bck: 1.5 x both side towers

cut: $|\eta^{\text{rel}}| < 0.6$, $|\phi^{\text{rel}}| < 0.9$

Plug: sig: EM=2x2 blocks, HAD=3x3 blocks

bck: EM=2x far strip, HAD=3x far strip

cut: $|\eta^{\text{rel}}| < 0.9$, $|\phi^{\text{rel}}| < 0.9$

GFLASH Lateral Profile Tuning

$$T(r) = \frac{2 r R_0^2}{(r^2 + R_0^2)^2}$$

- r: radial distance from shower center
- z: shower depth

$$\langle R_0(E_{\text{inc}}, z) \rangle = [R_1 + (R_2 - R_3 \ln E_{\text{inc}}) z]^n$$

core term R_1 **spread term Q**

- shower depth
- incident particle energy

- HAD and EM compartment provide complementary information about the shower development → useful to constrain R_1 and Q .
- (R_1, Q) is scanned at fixed energy bins and simulated E/p profiles compared with reference data: $\chi^2 = [\chi^2(\text{EM})/N_1 + \chi^2(\text{HAD})/N_2]/N$.
- R_2 and R_3 determined from energy dependence of Q using R_1 constraint.

Tuning Details

- Data: Focus on Minimum Bias data.
 - sufficient single isolated IO tracks Plug(Crack) up to 20(14)GeV/c
- Simulation: particle gun (FAKEEV) + cdfSim/ProductionExe 6.1.4
 - 16 particles per event within $|\eta|=0.3-2.0$
 - Pion/Kaon/Proton=.6/.3/.1
 - flat spectrum, momentum weighting of E/p histograms
- For performance reasons **no Pythia Minimum Bias events** added for background modeling – is ok because...
 - we are looking at the response relative to target tower
 - lateral profiles are normalized to absolute E/p response of data
 - correction procedure for uncorrelated background
- Much higher MC statistics w.r.t. previous iteration and finer scan grid.
- Improved sensitivity by considering E/p profile of five instead of three adjacent towers (for $p < 8\text{GeV}/c$):
 - granularity in Plug finer than in Central

Dependence on E/p Profile Definition

new Central lateral plus
old Plug absolute response

Plug

Gaussian means

E/p Dependence on the Lateral Profile

- Limited signal acceptance region causes an interdependence between lateral and absolute response. Effect is moderate in Central but more drastic in Plug/Crack.
- New profiles are narrower at $<5\text{GeV}$ and broader at $>5\text{GeV}$
→ (a) more leakage (b) less leakage

MC/Data
comparison
in Gen-5

- If Gen-5 assumptions on lateral profile parameters*) are wrong, the simulated energy scale in the plug has perhaps a bias.
*) derived using SISA tracks up to $5\text{GeV}/c$ + H1 default for $>5\text{GeV}$

E/p Dependence on Lateral Profile (Wall)

tower 6

tower 7

tower 8

- Effect of varying the lateral profile core parameter R_1 from 0.05 to 0.50.
 NB: R_1 values used in Gen-5: 0.490 ($p < 5\text{GeV}$), 0.015 ($p > 5\text{GeV}$)

E/p Dependence on Lateral Profile (Crack)

tower 9

tower 10

tower 11

- Drastically increasing effect starting at tower 11.

E/p Dependence on Lateral Profile (Plug)

tower
15

Conclusions

- Have (almost) final profiles for Plug.
 - Plug parameters similar to Central values.
 - Lateral shower core consistently at ~ 0.2 .
 - Loosely constrained lateral spread term is set to give a reasonable description of the data.
- Simulated Plug scale in Gen-5/6 probably biased due to former lateral profile mismatch between data and MC.
 - $p < 5\text{GeV}$: Need to decrease TOT/p by $\sim 20\%$.
 - $p > 5\text{GeV}$: Need to increase TOT/p by $\sim 15\%$.
- Absolute E/p tuning for Gen-7 in Plug/Crack in progress...
